**Abstract:** Consider a variety over a finite field. The number of points over the field is not only an invariant of the variety, but also of its “scissors congruence” type: if we cut up the variety into locally closed pieces, and rearrange those pieces into another variety, the number of points does not change. Moreover, if we have an automorphism of a variety, the permutation induced on the points is similarly an invariant of the automorphism. In this talk we will discuss a way of enhancing this invariant to an invariant which can distinguish different types of automorphisms and use it to detect some interesting structures in the higher  $K$ -theory groups of varieties.
